Dear Artiom Kovnatsky,

Thank you for submitting your work to arXiv.

Your submission has been received and is under consideration. The temporary submission number is: submit/7445251.

As with all submissions, this work will go through technical and moderation checks. You will be contacted by arXiv when the work is announced or if any issues are identified.

Our goal is to screen and announce papers as quickly as possible while ensuring that papers meet long-term archival standards. Generally, this process takes two business days, with announcements occurring at 20:00 ET, Sunday through Thursday.

You can make changes and view the current status of the submission from your user dashboard: <https://arxiv.org/user/>.

Below is a copy of the submission information.

Regards,
arXiv Support

Title: VKB-Training: Epistemically Categorized Training Data for Hallucination
Reduction in Large Language Models

Authors: Artiom Kovnatsky

Categories: [cs.AI](#) [cs.CL](#) cs.LO

Comments: 8 pages, 3 tables. LLMs were used. Zenodo preprint. Prepared for NeurIPS 2026 Workshop (workshop version will omit Section 7: Ethical Data Sourcing). Methodology and architecture proposal; experimental protocol provided but not yet executed. Licensed under S.V.E. Meta-License v4.0 (CC BY-NC-SA 4.0 + SVE Addendum)

DOI: 10.5281/zenodo.19430119

\\

We hypothesize that large language models hallucinate largely because their training data carries no epistemic metadata: facts, hypotheses, value judgments, and acknowledged unknowns occupy the same embedding space with identical weight. We propose VKB-Training (Verified Knowledge Base Training), a data-centric approach that assigns each training sample a five-category epistemic tag (Fact, Model, Value, Hypothesis, BlindSpot), a calibrated confidence score, and a provenance chain. We introduce a four-stage hybrid annotation pipeline: (1) AI triangulation, where inter-model disagreement signals normative content; (2) human sampling with axiom extraction; (3) expert calibration with reputation weighting; (4) formal logical consistency filters. Three training mechanisms are proposed: a confidence-weighted loss function that down-weights uncertain claims and unlearns falsified content; provenance-aware attention biasing verified tokens; and a BlindSpot objective that maximizes output entropy at marked knowledge gaps. We provide a falsifiable experimental protocol with pre-specified success thresholds on TruthfulQA, HaluEval, and FActScore. VKB-Training reframes hallucination as a data problem and proposes a solution at the layer where the problem originates. This is a methodology paper; no experiments have been conducted yet. All claims are hypotheses submitted for empirical testing.
